The nanostructured phosphor particles of $Y_2O_3:Eu^{3+}$ and $(Y_{1-x}Gd_x)_2O_3:Eu^{3+}$ ($x=0.25, 0.50, 0.75$) systems were synthesized through aerosol method. The corresponding nitrate solutions were ultrasonically atomized (1.3MHz) and the obtained aerosol was decomposed at 900°C. The as-prepared powders were thermally treated at 1000-1200°C/12h. The employed synthesis method assured formation of spherical, full, non-agglomerated and polycrystalline particles with crystallite size around 20nm. Powders structural and morphological features were investigated by means of XRD, SEM, TEM/SAED and HRTEM/FFT methods. Functional properties were examined through photoluminescent analysis. A detail study of the emission spectra after excitation with 393nm wavelength and of the decay lifetimes for Eu^{3+} ion 5D_0 and 5D_1 levels gave an insight into improved luminescent properties of the obtained powders. The emission spectra showed typical $Eu^{3+} {}^5D_0 \rightarrow {}^7F_i$ ($i=0, 1, 2, 3, 4$) transitions with dominant red emission at 611nm, while the lifetime measurements gave an insight into the effect of dopant concentration (5 and 10 at%) and its distribution into host lattice according to the applied thermal treatment. Additionally, luminescent properties were correlated with the obtained structural and morphological features of the synthesized powders.

The summarized microstructural data and characteristics of emission spectra for $Y_2O_3:Eu^{3+}$ system

The presence of *Fm-3m* phase in as-prepared sample with highest Gd content was additionally confirmed by SAED analysis (correspond to $Gd_2Te_6O_{15}$ - JCPDS 37-1400, $a=5.61 \text{ \AA}$)

The increase in gadolinium content leads to the increase of lattice parameters and consequent pick shift towards lower 2θ angles.

Thermal treatment at 1100°C/12h led to the presence of solely bcc *Ia-3* phase

The summarized microstructural data and characteristics of emission spectra for $(Y_{1-x}Gd_x)_2O_3:Eu^{3+}$ system at 1100°C

$\Delta E(Y_2O_3) = 355 \text{ cm}^{-1}$, $\Delta E(Gd_2O_3) = 318 \text{ cm}^{-1}$, $\tau(Gd_2O_3)_{avr} = 1.1 \text{ ms}$

Mixed oxides obtained through spray pyrolysis method have higher lifetimes in comparison to bulk form of pure $Y_2O_3:Eu^{3+}$ and $Gd_2O_3:Eu^{3+}$ oxides. For the case of $(Y_{0.25}Gd_{0.75})_2O_3$ with 10 at% of Eu^{3+} quit strong luminescence quenching is observed resulting in poorer properties even compared to bulk.

Applied synthesis method (spray pyrolysis) led to the formation of nanostructured powders having longer lifetimes in comparison to $Y_2O_3:Eu^{3+}$ in its bulk form ($\tau({}^5D_0 \rightarrow {}^7F_2)_{theor} = 1.0 \text{ ms}$).

Cross-relaxation effect is stronger in the case of as-prepared samples, indirectly depicting more homogeneous distribution of Eu^{3+} ions in the case of the annealed samples

$$I(t) = I(0)e^{-\frac{t}{\tau}}$$

$$\tau_{avr} = \frac{\int tI(t)dt}{\int I(t)dt}$$
